Useful relationship is:  $M = (gRT)/(PV)$ . Significant intermolecular attraction exists at temperatures not far above boiling point.

Therefore, the compressibility of the gas is greater and the value of  $PV$  is smaller than predicted.

This would lead to a higher value for the molecular weight than the true value.

1982

a) 2 points

Real molecules exhibit finite volumes, thus excluding some volume from compression.

Real molecules exhibit attractive forces, thus leading to fewer collisions with the walls and a lower pressure.

b) 3 points

$\text{SO}_2$  is the least ideal gas.

It has the largest size or volume.

It has the strongest attractive forces (van der Waals forces or dipole-dipole interactions).

c) 3 points

High temperature results in high kinetic energies.

This energy overcomes the attractive forces.

Low pressure increases the distance between molecules. (So molecules comprise a small part of volume or attractive forces are small)

Scoring Standards for Question #7 - - - - - (8 points total)

Constant <u>a</u> is related to the attractive forces that exist between real molecules.	1 point
Constant <u>b</u> is related to the fact that real molecules occupy space or volume.	1 point
H <sub>2</sub> S has a larger <u>a</u> value because H <sub>2</sub> is a polar molecule and therefore has stronger intermolecular forces.	1 point* 2 points
H <sub>2</sub> S has a larger <u>b</u> value because of its additional atom.	1 point**
The constant <u>a</u> correlates with the boiling point since it is related to the intermolecular forces which must be overcome in the process of boiling.	1 point* 1 point

\* 1 point granted in the absence of an explanation only if the constant is correctly identified somewhere in the discussion.

\*\* Explanation not required for point provided constant is correctly identified somewhere in the discussion.

Three volatile compounds X, Y, and Z each contain element Q. The percent by weight of element Q in each compound was determined. Some of the data obtained are given below.

<u>Compound</u>	<u>Percent by Weight of Element Q</u>	<u>Molecular Weight</u>
X	64.8%	?
Y	73.0%	104.
Z	59.3%	64.0

- (a) The vapor density of compound X at 27°C and 750. mm Hg was determined to be 3.53 grams per liter. Calculate the molecular weight of compound X.
- (b) Determine the mass of element Q. contained in 1.00 mole of each of the three compounds.
- (c) Calculate the most probable value of the atomic weight of element Q.
- (d) Compound Z contains carbon, hydrogen, and element Q. When 1.00 gram of compound Z is oxidized and all of the carbon and hydrogen are converted to oxides, 1.37 grams of CO<sub>2</sub> and 0.281 gram of water are produced. Determine the most probable molecular formula of compound Z.

Part a:  $PV = (\text{grams/m wt}) \times RT$

$$\text{m wt} = (3.53 \text{ grams/liter}) (0.0821 \text{ liter-atm/mole K}) \times (300 \text{ K}) (1/[750/760]) = 88.1 \text{ grams/mole} \quad (3 \text{ points})$$

OR

$$(3.53 \text{ grams/liter}) (760/750) (300/273) \times (22.4 \text{ liters/mole}) = 88.1 \text{ grams/mole}$$

OR other equivalent solutions

Part b: gram Q/mole X =  $0.648 \times 88.1 = 57.1$

$$\text{gram Q/mole Y} = 0.730 \times 104 = 75.9$$

$$\text{gram Q/mole Z} \times 0.593 \times 64.0 = 38.0$$

One correct (1 point)

All correct (1 additional point)

Part c: Masses in (b) must be integral multiples of atomic weight. Largest common denominator is 19. (1 point)

Note: Credit given for incorrect at. wt. if consistent with values in (b).

Part d: 1.37 grams CO<sub>2</sub> (1 mole/44.0 grams CO<sub>2</sub>)  
= 0.0311 mole CO<sub>2</sub>  $\equiv$  0.0311 mole C

$$0.281 \text{ gram H}_2\text{O} (1 \text{ mole}/18.0 \text{ grams H}_2\text{O}) \\ = 0.0156 \text{ mole H}_2\text{O} = 0.0312 \text{ mole H} \quad (2 \text{ points})$$

$$1.00 \text{ gram Z} (1 \text{ mole}/64 \text{ grams}) = 0.0156 \text{ mole Z}$$

Each mole Z contains 2 moles of CH, or 26 grams, which leaves  $(64 - 26) = 38$  grams, corresponding to 2 moles of Element Q. Mol. formula is C<sub>2</sub>H<sub>2</sub>Q<sub>2</sub>. (1 point)

## STANDARDS

(a) Reducing the temperature of a gas reduces the average kinetic energy (or velocity) of the gas molecules. This would reduce the number (or frequency) of collisions of gas molecules with the surface of the balloon (or decrease the momentum change that occurs when the gas molecules strike the balloon surface.) In order to maintain a constant pressure vs the external pressure, the volume must decrease. 1 pt.

↳ [If other 2 pts not awarded]

(b) The molecules of the gas do have volume. When they are cooled sufficiently, the forces of attraction that exist between them cause them to liquefy or solidify. 1 pt.

(c) The molecules of a gas are in constant motion so the HCl and NH<sub>3</sub> diffuse along the tube. Where they meet, NH<sub>4</sub>Cl is formed. Since HCl has a higher molar mass, its velocity (avg) is lower. Therefore it doesn't diffuse as fast as the NH<sub>3</sub>. 1 pt.

(d) The wind is moving molecules of air that are going mostly in one direction. Upon encountering a flag, they transfer some of their energy (momentum) to it and cause it to move (flep!). 1 pt.

5.

Represented above are five identical balloons, each filled to the same volume at 25°C and 1.0 atmosphere pressure with the pure gases indicated.

- Which balloon contains the greatest mass of gas? Explain.
- Compare the average kinetic energies of the gas molecules in the balloons. Explain.
- Which balloon contains the gas that would be expected to deviate most from the behavior of an ideal gas? Explain.
- Twelve hours after being filled, all the balloons have decreased in size. Predict which balloon will be the smallest. Explain your reasoning.

The mixture in the flask is ignited by a spark, and the reaction represented below occurs until one of the reactants is entirely consumed.

(d) Give the mole fraction of all species present in the flask at the end of the reaction.
